CDIS vs Superview: Presentation Briefing

Guide for presenting and defending the comparison of CDIS and Superview detections · SSC CGL 2026 (exam 42) · 16 Oct (Shifts 2–3), 22, 23, 24, 27 and 28 Oct 2026 · data snapshot: Superview exports of 29–30 Oct 2026, CDIS database of 30 Oct 2026

1. The message in one sentence

> Of the alerts each system raised, the client accepted **7.4% of CDIS detections** against **0.6% of Superview events**: CDIS delivers about twelve times as many useful alerts per alert reviewed, consistently on every day, every shift and in every analytic that both systems run.

7.4% vs 0.6%	2,094 vs 288	13.6 vs 169	16 of 16
accepted by the client	accepted alerts	alerts reviewed per accepted alert	day-shifts won by CDIS

Positioning. Present this as a comparison of *usefulness to the client*, not of raw alert counts. The client's accept or reject decision is the common yardstick for both systems, and both systems were measured on the same days, shifts and centres.

2. How to start (first three minutes)

SUGGESTED OPENING

"Thank you for your time. Today I will compare two detection systems, CDIS and Superview, on the same exam: SSC CGL 2026, across six exam days and all shifts. The question is simple: *when a system raises an alert, how often does the client find it worth accepting?* I will first explain how we measured, then show the headline result, then how consistent it is, and finally what it means operationally. I will also be open about the limits of the comparison."

Establish credibility before the numbers

- **Same scope for both systems.** Same exam, same days, same shifts. CDIS detections are limited to the centres that were running that shift. Superview events are the full export of each session.
- **Same yardstick.** Client acceptance. Accepted counts as accepted; rejected and pending both count as not accepted, for both systems.
- **Same-event matching.** An event is the same when it is on the same camera, same analytic and within ±3 minutes.
- **Independent verification.** Every figure was recomputed from the raw Superview exports, the Superview camera reports and the CDIS database. Cameras and detection counts were also checked against the CDIS client reports.
- **Disclosed exclusions.** 16 Oct Shift 1 is excluded. CDIS did not run on 23 Oct Shift 3. That leaves 17 day-shifts, 16 of them with CDIS data.

3. Presentation flow (suggested 20–25 minutes)

Slide 1 · Context and method (2 min)

Exam, dates, systems compared, data sources, the definition of "accepted", and the exclusions above. Close with: "Everything that follows uses these definitions for both systems."

Slide 2 · Headline result (3 min)

- Superview raised **48,657** events; the client accepted **288** (0.6%).
- CDIS raised **28,410** detections (42% fewer); the client accepted **2,094** (7.4%).
- CDIS therefore delivered **7.3 times as many accepted alerts** with 42% fewer alerts.

KEY LINE

"More alerts is not better. What matters is how many of them the client can act on."

Slide 3 · Effort per useful alert (2 min)

A reviewer examines about **169 Superview events** to reach one accepted event, against about **13.6 CDIS detections**: roughly a **12-fold reduction** in review effort. Tie this to reviewer time and to the risk that genuine alerts are lost among noise.

Slide 4 · Consistency (3 min)

- CDIS had the higher accepted rate in **16 of 16** day-shifts with CDIS data. Range: CDIS 4.2%–12.8%; Superview 0.1%–1.1%.
- Every exam day and every shift favours CDIS (table below). Shift 1: 6.3% vs 0.7%; Shift 2: 9.5% vs 0.6%; Shift 3: 6.3% vs 0.5%.

Day	Superview events	Accepted	Rate	CDIS detections	Accepted	Rate
16 Oct	5,627	26	0.5%	3,097	256	**8.3%**
22 Oct	8,744	51	0.6%	2,846	157	**5.5%**
23 Oct	8,884	68	0.8%	3,442	168	**4.9%**
24 Oct	9,029	20	0.2%	4,534	453	**10.0%**
27 Oct	8,333	48	0.6%	7,507	567	**7.6%**
28 Oct	8,040	75	0.9%	6,984	493	**7.1%**

KEY LINE
"This is not one good day. The advantage appears every day and in every shift."

Slide 5 · Analytic by analytic (4 min)

CDIS has the higher accepted rate in all 10 analytics that both systems run. Highlight three stories:

- **Phone (Server Room):** CDIS 86 accepted from 472 alerts; Superview 53 accepted from 4,308. More accepted alerts at one ninth of the volume.
- **Phone (Inside Lab):** Superview raised 5,615 events and none was accepted; CDIS raised 80 and 11 were accepted (13.8%).
- **Crowd (Entry/Exit):** Superview 9,858 events, 1 accepted; CDIS 2,970 detections, 108 accepted.

Analytic	Superview events	Accepted	Rate	CDIS detections	Accepted	Rate
Invigilator Static	862	181	21.0%	2,993	1,449	**48.4%**
Phone (Server Room)	4,308	53	1.2%	472	86	**18.2%**
Phone (Inside Lab)	5,615	0	0.0%	80	11	**13.8%**
Server Room Threshold	862	13	1.5%	385	44	**11.4%**
Close Proximity	3,137	2	0.1%	128	9	**7.0%**
Zero Person	2,433	9	0.4%	861	46	**5.3%**
Crowd (Entry/Exit)	9,858	1	0.0%	2,970	108	**3.6%**
Entry/Exit Movement	6,075	8	0.1%	9,980	231	**2.3%**
Less than 5 people in a lab	8,681	16	0.2%	10,431	109	**1.0%**
Intruder	2,474	4	0.2%	109	1	**0.9%**

Slide 6 · Where the two systems agree, and where only CDIS finds value (3 min)

- **Jointly detected events:** 3,277 Superview events were matched by 2,850 CDIS detections. The client accepted 114 of those CDIS detections (4.0%) but only 35 of the Superview events (1.1%): a rate 3.7 times as high on the same incidents.
- **Additional value:** 1,980 client-accepted CDIS detections (94.6% of CDIS accepted) had no Superview event for the same camera and analytic within ±3 minutes.

Slide 7 · Operational impact and close (3 min)

- Pending (unreviewed) alerts: 21,851 for Superview against 12,066 for CDIS (45% fewer), which lowers the review backlog.
- CDIS's camera set per shift is larger (average 4,391 cameras, against 4,015 scheduled in Superview, which excludes an average of 1,510 cameras per session).

SUGGESTED CLOSING
"Across six exam days, CDIS gave the client about twelve times the acceptance rate and about twelve times less review effort per useful alert, in every shift and every shared analytic. We recommend using CDIS as the primary detection source and focusing the next phase on tuning the few analytics where the acceptance rate is still low."

4. Cheat sheet: numbers to remember

Measure	Superview	CDIS
Alerts raised	48,657	28,410
Accepted by the client	288 (0.6%)	2,094 (7.4%)
Pending / rejected	21,851 / 26,518	12,066 / 14,250
Alerts reviewed per accepted alert	169	13.6
Accepted rate among reviewed alerts only (accepted ÷ (accepted + rejected))	1.1%	12.8%
Accepted rate on jointly detected events	1.1%	4.0%
Accepted alerts with no counterpart in the other system	253	1,980
Average cameras online per shift	3,834	3,766

5. Anticipated questions and recommended answers

Answer plainly and concede what is true. Credibility on the points that favour Superview is what makes the CDIS case believable.

"Superview raises far more events. Isn't it detecting more?"	It raises 1.7 times as many events, but the client accepted 7.3 times as many CDIS alerts. A larger alert count adds review work; it adds value only where alerts are accepted. For example, Superview's Phone (Inside Lab) raised 5,615 events with none accepted.
"You count pending as rejected. Isn't that unfair?"	The same rule applies to both systems. The share of alerts still pending is similar (44.9% Superview, 42.5% CDIS), so it does not favour either. Considering only reviewed alerts (accepted ÷ accepted plus rejected), the rates are 1.1% for Superview and 12.8% for CDIS, a 12-fold gap. The accepted rates in this report are lower bounds for both.
"Superview has a higher camera online percentage."	True as reported (95.5% against 85.6%), but the measures differ: Superview counts a camera online if it was up for at least one minute of the shift; CDIS counts it online if it was classified in the shift's latest run, against a larger camera set. In absolute terms the number of online cameras is comparable (about 3,834 for Superview and 3,766 for CDIS per shift). Camera availability is a separate topic from detection usefulness.
"Superview has alerts that CDIS does not, such as Monitor Tampering."	Correct. Monitor Tampering is an alert type CDIS does not operate; Superview raised 4,352 such events and 1 was accepted. Equally, 253 Superview events accepted by the client had no CDIS counterpart, while 1,980 accepted CDIS detections had no Superview counterpart. The comparison supports using CDIS as the primary source; any specific Superview-only capability can be reviewed separately.
"7.4% still looks low."	Agreed that both are low in absolute terms, and part of the gap is pending review. The relevant point is relative: CDIS is 12 times as high, and its low-acceptance results are concentrated in a few analytics (next question) that can be tuned.
"Which CDIS analytics are weak?"	Be candid: Less than 5 people in a lab (10,431 detections, 1.0% accepted), Entry/Exit Movement (9,980, 2.3%) and Intruder (109, 0.9%). Even there CDIS is above Superview (0.2%, 0.1% and 0.2% respectively). These are the priorities for threshold tuning.
"Why were 16 Oct Shift 1 and 23 Oct Shift 3 left out?"	16 Oct Shift 1 is excluded from this report. CDIS did not run on 23 Oct Shift 3, so there is nothing to compare; it is not counted as a CDIS result. The conclusion rests on the 16 day-shifts with CDIS data, all of which favour CDIS.
"Is the matching method reliable?"	Same camera, same analytic, within ±3 minutes, with cameras identified by device, camera number and centre code (several centres share device and camera numbers). The numbers were recomputed independently from the raw exports and database and matched the report.
"Could the data have changed?"	Client review continues, so statuses move over time. This report is a fixed snapshot (CDIS database of 30 Oct 2026). Since the snapshot the client has moved further pending detections to accepted or rejected (at the last check the CDIS accepted count was 2,127 against 2,094 here), which does not change the conclusion. To refresh, the report and this briefing should be regenerated together.
"Why not cite Invigilator Static?"	CDIS records a broader set of invigilator alerts under that name than Superview's "Invigilator Not Moving", so the two are not like-for-like. It is included in the totals but not used as evidence of an advantage.

6. Do and do not

Do

- Lead with the definition of "accepted" and apply it equally to both systems.
- Concede Superview's higher online percentage, Monitor Tampering and the 253 Superview-only accepted events before being asked.
- Use ratios (12×, 3.7×) together with the absolute numbers.
- Finish with a clear request: use CDIS as the primary source, and tune the lowest-performing CDIS analytics.

Do not

- Claim CDIS detects "all" violations or that Superview detects "nothing": the data shows relative usefulness to the client, not completeness.
- Present the acceptance rate as technical accuracy. It reflects client review decisions and is a lower bound while items remain pending.
- Quote Invigilator Static, or the camera online percentage, as an advantage.

7. Data and method notes (appendix)

- **Superview events:** Events Report exports of every session, 16–27 Oct exported on 29 Oct 2026 and 28 Oct on 30 Oct 2026; Verified =

Accepted.

- **Superview cameras:** Detailed Report of each session (status, scheduled flag, online and offline minutes over the shift window).
- **CDIS detections:** database table camera_report_rtsp (exam 42), pushed to the client, limited to the centres running that shift. Detections left out by that rule are listed in the report's Method section.
- **CDIS cameras:** cameras of the centres running the shift; online = classified in the shift's latest classification run. For 28 Oct there is no client report file, so these were computed from the database using the same method, which reproduced all 15 available client reports exactly.
- **Status mapping:** CDIS Accepted = accepted by the client; Rejected = removed from the client and not accepted; Pending = no client action. Superview Verified = Accepted.
- **Source report:** Superview_vs_CDIS_16-27Oct_All_Shifts_Report.html (17 day-shifts after exclusions).
